

Undersampling is a technique used to fix imbalanced datasets by reducing the number of samples in the majority class so that it matches the minority class.

◆ Example:

If your dataset has:

- 900 "No Disease"
- 100 "Disease"

Then undersampling will randomly select 100 samples from "No Disease" to balance both classes.

Use When:

- You have lots of majority class data
 - Model training time needs to be reduced
-

Be Careful:

- It may remove useful information from the majority class
- Can lead to underfitting
