

Splitting of data means dividing your dataset into parts so you can train your model on one part and test it on another to check how well it works.

In easy words:

It's like studying from some chapters (training) and then giving a test from different chapters (testing) to see if you really learned well.

Common splits:

- Training set – used to teach the model
 - Testing set – used to check model's accuracy
 - (Sometimes also a Validation set – used to tune model settings)
-

Most common split:

80% Training, 20% Testing
